## ABSTRACT

We present an analytical formulation of gravitational lensing using familiar triaxial power-law mass distributions, where the 3-dimensional mass density is given by  $\rho(X, Y, Z) = \rho_0 \left[ 1 + \left( \frac{X}{a} \right)^2 + \left( \frac{Y}{b} \right)^2 + \left( \frac{Z}{c} \right)^2 \right]^{-\nu/2}$ . The deflection angle and magnification factor are obtained analytically as Fourier series. We give the exact expressions for the deflection angle and magnification factor. The formulae for the deflection angle and magnification factor given in this paper will be useful for numerical studies of observed lens systems. An application of our results to the Einstein Cross can be found in Chae, Turnshek, & Khersonsky (1998). Our series approach can be viewed as a user-friendly and efficient method to calculate lensing properties that is better than the more conventional approaches, e.g., numerical integrations, multipole expansions.

*Subject headings:* cosmology: gravitational lensing — galaxies: structure — methods: analytical

## 1. Introduction

Gravitational lenses in nature usually consist of a primary lensing galaxy and, in many cases, perturbation field caused by, for example, nearby galaxies and clusters of galaxies along the sight-line (see Keeton, Kochanek, & Seljak 1997). Thus, modeling an observed lens requires the construction of a realistic mass model, including accounting for any perturbation that may be present. This paper develops a (semi-)analytical method to calculate lensing due to the primary mass distribution.

Lensing objects (e.g. galaxies or galaxy clusters) show, in general, 3-dimensional mass distributions which are non-spherically symmetric. Elliptical galaxies are known to be triaxial in shape, as well as oblate and prolate (see, e.g., Ryden 1992). Spiral galaxies can be considered flattened spheroids. Clusters of galaxies are also known to be non-spherical in shape. Gravitational lensing by these concentrations of mass in the universe is difficult to deal with mathematically. For a projected surface density of elliptical shape Schramm (1990) introduced a relatively simple formulation equivalent to the early formulation by Bourassa, Kantowski, & Norton (1973) and Bourassa & Kantowski (1975, see also Bray 1984). In the above formulations the deflections are given as integrals. Thus, one can deal with lensing by elliptical mass distributions through numerical integrations. While numerical integration is a way of dealing with lensing by elliptical mass distributions, it has not been preferred by most researchers.

To “simulate” real lenses in nature while avoiding mathematical complexities or costly numerical integrations, several lens models have been considered in the literature. First, circularly symmetric lenses perturbed by an external shear term (also called a quadrupole term) were used (e.g. Chang & Refsdal 1979, 1984; Kovner 1987a; Kochanek 1991; Wambsganss & Paczyński 1994). In addition, Kochanek (1991) considered other types of perturbations (internal & mixed). This approach has the great advantage of mathematical simplicity. It could be a good approximation of a real lens in some situations. However, this approach is somewhat artificial and does not take into account the real distributions of mass. Secondly, lenses with elliptical deflection potentials were studied (e.g. Kovner 1987b,c; Blandford & Kochanek 1987a; Kochanek & Blandford 1987; Kochanek et al. 1989). Elliptical potentials are easier to handle than elliptical mass distributions. For a small ellipticity elliptical potentials correspond to physical (elliptical) mass distributions via the Poisson equation, but for a larger ellipticity (e.g.  $0.5 \lesssim \epsilon$ ) the corresponding mass distributions obtain unphysical dumbbell shapes (see Kassiola & Kovner 1993). Thirdly, a multipole expansion of elliptical mass distributions was considered by Schneider & Weiss (1991) who expanded a 2-dimensional distribution of mass with elliptical symmetry and calculated the corresponding potential

coefficients. Thus, in this approach a (nearly) elliptical mass distribution is described by the several lowest-order terms in the expansion. Lastly, for a few special cases the deflection angles were obtained in simple (closed) forms. For elliptical “isothermal” lenses (where the surface mass density  $\Sigma \sim r^{-(\nu-1)}$  [ $\nu = 2$ ] at large  $r$ ), the deflection angles were calculated by Kassiola & Kovner (1993) and Kormann, Schneider, & Bartelmann (1994). Kassiola & Kovner (1993) also calculated the deflection angles for other integer values of  $\nu$ , i.e.  $\nu = 3, 4, 5$ , etc. For singular power-law mass distributions, the deflection angle was obtained by Grogin & Narayan (1996).

All of the above lens models avoid numerical integrations and are relatively easy to use. However, we know that most (if not all) of them are limited in their applications. For the generalized non-circular power-law mass distributions where the parameter  $\nu$  and core radius are arbitrary, numerical integrations (Bourassa & Kantowski 1975; Schramm 1990) and multipole expansions (Schneider & Weiss 1991) have been considered and the former approach has sometimes been used to calculate lensing properties (e.g. most recently by Keeton and Kochanek 1997). In the Schneider & Weiss (1991) approach an elliptical mass distribution is expanded and several lowest-order terms are used to describe the original mass distribution. This approximation can be effective for a less elliptical mass distribution because only a few terms suffice to describe the original mass distribution. However, for a highly elliptical mass distribution this approach becomes increasingly less effective because many terms are necessary to approximate the original mass distribution. Also, we do not, at present, find any examples in the literature where this approach was used. For the above reasons this approach will not be further discussed. In this paper we present an analytical approach to lensing by the generalized power-law mass distributions. In our approach all of the terms in the infinite series can be integrated in closed forms (as hypergeometric functions), and the series themselves have well-defined convergence properties. As a result, we obtain the deflection and magnification in ready-to-use forms. Our approach is a straightforward and user-friendly way to calculate lensing properties more effectively than the more conventional methods mentioned above. Our results can be used by those who want to use (exactly) elliptical surface mass densities (or, 3-dimensional triaxial mass distributions directly) and who do not want to use numerical integrations. We applied our results to the Einstein Cross and they were very effective (Chae, Turnshek, & Khersonsky 1998). Our approach is as follows.

We represent the deflection potential as a Fourier series for an arbitrary projected surface density. From the deflection potential we obtain the deflection angle as a series. We calculate the projected surface mass density of the triaxial power-law mass distribution and thus relate the parameters of the surface mass density to those of the 3-dimensional mass density. We calculate the coefficients in the series of the

deflection angle for the surface density. We obtain expressions for the deflection angle and magnification factor.

The above procedures are described in §2; the details of mathematics can be found in the Appendices. In §3 we describe how the behaviors of critical curves and caustics depend on the parameters of the elliptical power-law mass distributions. Concluding remarks are given in §4.

## 2. Mathematical Formulation

### 2.1. Basic Equations, Definitions and Notation

In this subsection we briefly summarize the basic equations of gravitational lensing and define the coefficients of the series of the deflection potential. Our treatment of lensing is based on the scalar potential formalism given by Schneider (1985) and Blandford & Narayan (1986). Our notation is similar to that used by Schneider, Ehlers, & Falco (1992, hereafter SEF) and Blandford & Kochanek (1987b).

When a light ray emitted by a quasar (i.e. the source) at angular diameter distance  $D_s$  passes through a transparent distribution of mass (i.e. the deflector) at  $D_d$ , the light ray experiences a deflection and the condition for the deflected light ray to reach the observer is given by the lens equation (SEF)

$$\vec{\eta} = \frac{D_s}{D_d} \vec{\xi} - D_{ds} \hat{\alpha}(\vec{\xi}). \quad (1)$$

Here  $\vec{\eta}$  is the position vector of the quasar on the source plane and  $\vec{\xi}$  is the impact vector of the light ray on the lens plane, both with respect to the optical axis (defined below). The parameter  $\hat{\alpha}(\vec{\xi})$  is the deflection angle and  $D_d, D_s$  and  $D_{ds}$  are the angular diameter distances to the deflector, the source, and from the deflector to the source, respectively. The optical axis is defined as the infinite line joining the observer and the center of mass of the lens. By introducing an arbitrary length scale  $\xi_0$  and defining  $\vec{x} = \vec{\xi}/\xi_0$  (deflector vector),  $\vec{x}_s = \vec{\eta}/(\xi_0 D_s/D_d)$  (source vector), the above equation becomes the dimensionless lens equation

$$\vec{x}_s = \vec{x} - \vec{\alpha}(\vec{x}), \quad (2)$$

where  $\vec{\alpha}(\vec{x})$  is the scaled deflection angle which is related to the deflection potential  $\psi(\vec{x})$  by  $\vec{\alpha}(\vec{x}) = \nabla \psi(\vec{x})$ . The deflection potential is given in polar coordinates (SEF) by

$$\psi(r, \phi) = \frac{1}{\pi} \int_0^{2\pi} d\phi' \int_0^\infty \kappa(r', \phi') \ln[r^2 + r'^2 - 2rr' \cos(\phi - \phi')]^{1/2} r' dr', \quad (3)$$

where the dimensionless surface density  $\kappa(\vec{x})$  is obtained by dividing the surface density  $\Sigma(\vec{\xi})$  by  $\Sigma_{cr}$ , i.e.  $\kappa(\vec{x}) = \Sigma(\xi_0 \vec{x})/\Sigma_{cr}$ , and the critical surface mass density  $\Sigma_{cr}$  is defined by  $\Sigma_{cr} = (4\pi G/c^2)^{-1}(D_d D_{ds}/D_s)^{-1}$ .

By expanding the logarithmic function in equation (3) for  $r' > r$  and  $r' < r$  respectively, the deflection potential can be written as

$$\begin{aligned} \psi(r, \phi) = & \frac{A_0(r)}{\pi} \ln r - \sum_{n=1}^{\infty} \frac{\cos n\phi}{n\pi} \left[ \frac{B_n(r)}{r^n} + r^n D_n(r) \right] \\ & + \frac{F(r)}{\pi} - \sum_{n=1}^{\infty} \frac{\sin n\phi}{n\pi} \left[ \frac{C_n(r)}{r^n} + r^n E_n(r) \right], \end{aligned} \quad (4)$$

and the deflection angle components are

$$\begin{aligned} \alpha_r = & \frac{1}{\pi r} A_0(r) \\ & - \frac{1}{\pi r} \sum_{n=1}^{\infty} \left\{ \cos(n\phi) \left[ -\frac{B_n(r)}{r^n} + r^n D_n(r) \right] + \sin(n\phi) \left[ -\frac{C_n(r)}{r^n} + r^n E_n(r) \right] \right\}, \end{aligned} \quad (5)$$

$$\alpha_\phi = \frac{1}{\pi r} \sum_{n=1}^{\infty} \left\{ \sin(n\phi) \left[ \frac{B_n(r)}{r^n} + r^n D_n(r) \right] - \cos(n\phi) \left[ \frac{C_n(r)}{r^n} + r^n E_n(r) \right] \right\}, \quad (6)$$

where the coefficients of the series are defined as follows:

$$A_0(r) = \int_0^{2\pi} d\phi' \int_0^r \kappa(r', \phi') r' dr', \quad (7)$$

$$B_n(r) = \int_0^{2\pi} d\phi' \cos n\phi' \int_0^r \kappa(r', \phi') r'^{n+1} dr', \quad (8)$$

$$C_n(r) = \int_0^{2\pi} d\phi' \sin n\phi' \int_0^r \kappa(r', \phi') r'^{n+1} dr', \quad (9)$$

$$D_n(r) = \int_0^{2\pi} d\phi' \cos n\phi' \int_r^\infty \kappa(r', \phi') \frac{1}{r'^{n-1}} dr', \quad (10)$$

$$E_n(r) = \int_0^{2\pi} d\phi' \sin n\phi' \int_r^\infty \kappa(r', \phi') \frac{1}{r'^{n-1}} dr', \quad (11)$$

and

$$F(r) = \int_0^{2\pi} d\phi' \int_r^\infty \kappa(r', \phi') \ln r' \cdot r' dr'. \quad (12)$$

From equation (2) the image magnification factor is given by

$$\mathcal{M} = \left[ \det \left| \frac{\partial \vec{x}_s}{\partial \vec{x}} \right| \right]^{-1}, \quad (13)$$

where  $\left( \frac{\partial \vec{x}_s}{\partial \vec{x}} \right)$  is the Jacobian matrix in  $\vec{x}_s = \vec{x}_s(\vec{x})$ . A point source at  $\vec{x}_s$  on the source plane forms an image at  $\vec{x}$  on the lens plane magnified by a factor of  $|\mathcal{M}|$ .

## 2.2. The Projected Surface Mass Density

The 3-dimensional triaxial power-law distribution of mass is described by

$$\rho(X, Y, Z) = \rho_0 \left[ 1 + \left( \frac{X}{a} \right)^2 + \left( \frac{Y}{b} \right)^2 + \left( \frac{Z}{c} \right)^2 \right]^{-\nu/2}, \quad (14)$$

where  $(X, Y, Z)$  are the body coordinates attached to the lensing object. The positive constants  $(a, b, c)$  represent the core sizes along each axis. In passing, we mention that a more conventional parameterization is obtained through  $b = au$  and  $c = av$ , where  $1 \geq u \geq v$  by convention. The constant  $\rho_0$  is the density at the center. The radial index  $\nu$  determines how the mass density decreases at large  $r$ . If  $\nu > 3$ , the lens has a finite total mass ( $M$ ) and  $\rho_0$  is related to the total mass by  $\rho_0 = M[2\pi abc B(3/2, \mu)]^{-1}$ , where  $\mu \equiv (\nu - 3)/2$  and  $B(a, b)$  is the Beta function. When  $\nu = 2$ , the mass distribution is called “isothermal” since the mass density decreases like the singular isothermal sphere at large  $r$ . A physical distribution of mass must satisfy  $\nu > 1$  because  $\nu = 1$  corresponds to a constant surface density on the lens plane (see eq. [15]).

Since a lensing galaxy (or any lensing object) can be oriented in an arbitrary direction relative to the lens plane, three parameters are needed to relate the body coordinates  $(X, Y, Z)$  to the lens coordinates  $(x, y, z)$ , where  $z$  is the direction toward the observer. These three parameters are the Eulerian angles  $(\alpha, \beta, \gamma)$  (see, e.g., Goldstein 1980). We have  $X_i = \sum_j a_{ij} x_j$ , where  $X_i = (X, Y, Z)$ ,  $x_j = (x, y, z)$ , and the transformation matrix  $(a_{ij})$  can be found in Goldstein (1980, eq. [4-47]) with  $i, j = 1, 2, 3$ . Using this transformation we find

$$1 + \frac{X^2}{a^2} + \frac{Y^2}{b^2} + \frac{Z^2}{c^2} = Az^2 + 2B(x, y)z + C(x, y),$$

where  $A = a_{13}^2/a^2 + a_{23}^2/b^2 + a_{33}^2/c^2$  and

$$\begin{aligned} B(x, y) &= B_1 x + B_2 y; \quad B_1 = \frac{a_{11}a_{13}}{a^2} + \frac{a_{21}a_{23}}{b^2} + \frac{a_{31}a_{33}}{c^2}, \quad B_2 = \frac{a_{12}a_{13}}{a^2} + \frac{a_{22}a_{23}}{b^2} + \frac{a_{32}a_{33}}{c^2}, \\ C(x, y) &= 1 + C_1 x^2 + C_2 y^2 + 2C_3 xy; \quad C_1 = \frac{a_{11}^2}{a^2} + \frac{a_{21}^2}{b^2} + \frac{a_{31}^2}{c^2}, \quad C_2 = \frac{a_{12}^2}{a^2} + \frac{a_{22}^2}{b^2} + \frac{a_{32}^2}{c^2}, \\ &\quad C_3 = \frac{a_{11}a_{12}}{a^2} + \frac{a_{21}a_{22}}{b^2} + \frac{a_{31}a_{32}}{c^2}. \end{aligned}$$

Now the 2-dimensional surface density on the lens plane can be evaluated as

$$\begin{aligned} \Sigma(x, y) &= \int_{-\infty}^{\infty} \rho(x, y, z) dz \\ &= 2^{2\mu+1} B(\mu + 1, \mu + 1) \frac{\rho_0}{\sqrt{A}} \frac{1}{[f(x, y)]^{\mu+1}}, \end{aligned} \quad (15)$$

where  $f(x, y) \equiv C(x, y) - [B(x, y)]^2/A$ . Note that  $\mu \equiv (\nu - 3)/2 > -1$ .

We rewrite  $f(x, y)$  as

$$f(x, y) = 1 + c_x x^2 + c_y y^2 + c_{xy} xy, \quad (16)$$

where  $c_x = C_1 - B_1^2/A$ ,  $c_y = C_2 - B_2^2/A$ , and  $c_{xy} = 2(C_3 - B_1 B_2/A)$ . In polar coordinates equation (16) becomes

$$f(r, \phi) = 1 + r^2[P + Q \sin(2\phi + S)], \quad (17)$$

where  $P = (c_x + c_y)/2$ ,  $S = \tan^{-1}[(c_x - c_y)/c_{xy}]$ , and  $Q = (c_x - c_y)/(2 \sin S)$ .

Equations (15) and (17) show that the projected surface density of a triaxial mass distribution (eq. [14]) is described by a set of concentric ellipses with constant ellipticity (see, e.g., Stark 1977). The ellipticity of an ellipse,  $\epsilon$ , is given by

$$\epsilon = 1 - \frac{r_{min}}{r_{max}} = 1 - \sqrt{\frac{1 - |e|}{1 + |e|}}, \quad (18)$$

where  $r_{min}$  and  $r_{max}$  are the semi-minor and semi-major axes of an ellipse, respectively, and  $e \equiv Q/P$ . The ratio  $|e|$  is a measure of the shape of an ellipse and  $0 \leq |e| < 1$ .

The dimensionless surface density as a function of the deflector vector is given by

$$\kappa(\vec{x}) = \kappa(r, \phi) = \frac{\kappa_0}{\{1 + r^2[P + Q \sin(2\phi + S)]\}^{\mu+1}}. \quad (19a)$$

Equation (19a) can be rewritten in the following more convenient form

$$\kappa(r, \phi) = \kappa_0 \left\{ 1 + \left( \frac{r}{r_c} \right)^2 [1 + e \cos 2(\phi - \phi_0)] \right\}^{-(\mu+1)}, \quad (19b)$$

where the “core radius”  $r_c \equiv 1/\sqrt{P}$  and the orientation angle  $\phi_0 \equiv \frac{\pi}{4} - \frac{S}{2}$ , which becomes the standard position angle (P.A., north through east) if  $e > 0$  (see also Keeton & Kochanek 1997). In equations (19a,b)

$$\kappa_0 = \frac{2^{2\mu+1} B(\mu + 1, \mu + 1) \rho_0}{\sqrt{A} \cdot \Sigma_{cr}}. \quad (20)$$

### 2.3. The Deflection Angle and Magnification Factor

The coefficients of the deflection angle (equations [7] - [11]) are calculated in Appendix A. Using the results of Appendix A, we are now ready to consider the full expressions for the deflection angle and magnification factor at  $\vec{x}$  on the lens plane due to the mass distribution given by equation (14) or equation

(19). From Appendix A, all odd-numbered coefficients vanish and the even-numbered coefficients can be written as follows by introducing three functions of  $r$  [ $I^{(0)}(r)$ ,  $I_{2m}^{(1)}(r)$ , and  $I_{2m}^{(2)}(r)$ ]:

$$A_0(r) = \kappa_0 \pi r I^{(0)}(r), \quad (21)$$

$$\begin{cases} B_{2m}(r) = \kappa_0 \pi r^{1+2m} I_{2m}^{(1)}(r) \cos(m\delta) \\ C_{2m}(r) = \kappa_0 \pi r^{1+2m} I_{2m}^{(1)}(r) \sin(m\delta) \end{cases}, \quad (22)$$

and

$$\begin{cases} D_{2m}(r) = \kappa_0 \pi r^{1-2m} I_{2m}^{(2)}(r) \cos(m\delta) \\ E_{2m}(r) = \kappa_0 \pi r^{1-2m} I_{2m}^{(2)}(r) \sin(m\delta) \end{cases}, \quad (23)$$

where  $\delta \equiv \pi/2 - S$ .

Now the deflection angle components, equations (5) and (6), can be written in the following simple forms

$$\alpha_r = \kappa_0 I^{(0)}(r) + \kappa_0 \sum_{m=1}^{\infty} \left[ I_{2m}^{(1)}(r) - I_{2m}^{(2)}(r) \right] \cos[m(2\phi - \delta)], \quad (24)$$

$$\alpha_\phi = \kappa_0 \sum_{m=1}^{\infty} \left[ I_{2m}^{(1)}(r) + I_{2m}^{(2)}(r) \right] \sin[m(2\phi - \delta)]. \quad (25)$$

Using the results of Appendix A,  $I^{(0)}(r)$ ,  $I_{2m}^{(1)}(r)$ , and  $I_{2m}^{(2)}(r)$  can be written as follows.

For  $r \leq 1/\sqrt{P - |Q|}$

$$I^{(0)}(r) = h(r) [\varepsilon_2(r)]^\mu \sum_{k=0}^{\infty} \sum_{l=0}^k (-1)^l \zeta_1(k, l, 0, \mu) [\varepsilon_2(r)]^l {}_2F_1(-l - \mu, -l - \mu; 1; \varepsilon_1(r)), \quad (26a)$$

for  $r > 1/\sqrt{P - |Q|}$  and  $\mu \neq 0$

$$I^{(0)}(r) = \frac{1}{\mu} \left[ \frac{1}{r \sqrt{P^2 - Q^2}} - h(r) [\varepsilon_2(r)]^\mu \sum_{k=0}^{\infty} [\varepsilon_2(r)]^k {}_2F_1(-k - \mu, -k - \mu; 1; \varepsilon_1(r)) \right], \quad (26b)$$

and for  $\mu = 0$

$$I^{(0)}(r) = \frac{1}{r \sqrt{P^2 - Q^2}} \ln \left[ \frac{\sqrt{P^2 - Q^2} \sqrt{(P^2 - Q^2)r^4 + 2Pr^2 + 1} + (P^2 - Q^2)r^2 + P}{\sqrt{P^2 - Q^2} + P} \right]. \quad (26c)$$

For  $r \leq 1/\sqrt{P - |Q|}$

$$\begin{aligned} I_{2m}^{(1)}(r) &= \left( -\frac{Q}{|Q|} \right)^m h(r) [\varepsilon_1(r)]^{\frac{m}{2}} [\varepsilon_2(r)]^\mu \\ &\times \sum_{k=0}^{\infty} \sum_{l=0}^k (-1)^l \zeta_1(k, l, m, \mu) [\varepsilon_2(r)]^l {}_2F_1(m - l - \mu, -l - \mu; m + 1; \varepsilon_1(r)), \end{aligned}$$

(27a)

and for  $r > 1/\sqrt{P - |Q|}$ , if  $\mu$  is not integer,

$$\begin{aligned}
 I_{2m}^{(1)}(r) &= - \left( -\frac{Q}{|Q|} \right)^m h(r) [\varepsilon_1(r)]^{\frac{m}{2}} \frac{\Gamma(\mu - m)}{\Gamma(\mu + 1)\Gamma(m + 1)} \\
 &\times \left\{ [\varepsilon_2(r)]^\mu \sum_{k=0}^{\infty} \frac{\Gamma(k + m + \mu + 1)}{\Gamma(k - m + \mu + 1)} [\varepsilon_2(r)]^k {}_2F_1(m - k - \mu, -k - \mu; m + 1; \varepsilon_1(r)) \right. \\
 &\quad \left. - [\varepsilon_2(r)]^m \sum_{k=0}^{\infty} \frac{\Gamma(k + 2m + 1)}{\Gamma(k + 1)} [\varepsilon_2(r)]^k {}_2F_1(-k, -k - m; m + 1; \varepsilon_1(r)) \right\}.
 \end{aligned} \tag{27b}$$

And for any  $r > 0$

$$\begin{aligned}
 I_{2m}^{(2)}(r) &= \left( -\frac{Q}{|Q|} \right)^m h(r) [\varepsilon_1(r)]^{\frac{m}{2}} [\varepsilon_2(r)]^\mu \zeta_2(m, \mu) \\
 &\times \sum_{k=0}^{\infty} [\varepsilon_2(r)]^k {}_2F_1(m - k - \mu, -k - \mu; m + 1; \varepsilon_1(r)).
 \end{aligned} \tag{28}$$

In equations (26), (27), and (28) we defined the following:

$$h(r) = \frac{r}{\sqrt{(1 + Pr^2)^2 - (Qr^2)^2}}, \tag{29}$$

$$\varepsilon_1(r) = \left[ 1 - \sqrt{1 - \left( \frac{Qr^2}{1 + Pr^2} \right)^2} \right] \left[ 1 + \sqrt{1 - \left( \frac{Qr^2}{1 + Pr^2} \right)^2} \right]^{-1}, \tag{30}$$

$$\varepsilon_2(r) = \frac{1}{2} \left[ \frac{1 + Pr^2}{(1 + Pr^2)^2 - (Qr^2)^2} + \frac{1}{\sqrt{(1 + Pr^2)^2 - (Qr^2)^2}} \right], \tag{31}$$

$$\zeta_1(k, l, m, \mu) = \frac{\Gamma(k + 1)\Gamma(k + \mu + 1)\Gamma(m + l + \mu + 1)}{\Gamma(l + 1)\Gamma(k - l + 1)\Gamma(\mu + 1)\Gamma(l + \mu + 1)\Gamma(m + k + 2)}, \tag{32}$$

and

$$\zeta_2(m, \mu) = \frac{\Gamma(m + \mu)}{\Gamma(m + 1)\Gamma(\mu + 1)}. \tag{33}$$

Note that  $0 \leq \varepsilon_1(r) < 1$  and  $0 < \varepsilon_2(r) \leq 1$  for  $0 \leq r < \infty$ . In equations (26) and (27), the range of  $r$  for each expression corresponds to the range for which the expression converges rapidly. Outside this range each expression will still converge but slowly. Equation (28) converges quickly for any  $r$  if  $m \geq 2$ , but converges very slowly for  $m = 1$  and  $(P + |Q|)r^2 \ll 1$ . For  $m = 1$  and  $(P + |Q|)r^2 \ll 1$ , an alternative form of  $I_{2m}^{(2)}(r)$  can be found in Appendix A (eq. [A9]), which converges very quickly. In cartesian coordinates the deflection angle is

$$\vec{\alpha} \equiv \alpha_x \hat{\mathbf{i}} + \alpha_y \hat{\mathbf{j}} = (\alpha_r \cos \phi - \alpha_\phi \sin \phi) \hat{\mathbf{i}} + (\alpha_r \sin \phi + \alpha_\phi \cos \phi) \hat{\mathbf{j}}. \tag{34}$$

The determinant of the Jacobian matrix  $(\frac{\partial \vec{x}_s}{\partial \vec{x}})$  is

$$\det \left[ \frac{\partial \vec{x}_s}{\partial \vec{x}} \right] = \begin{vmatrix} 1 - \psi_{,11} & -\psi_{,12} \\ -\psi_{,21} & 1 - \psi_{,22} \end{vmatrix}, \quad (35)$$

where

$$\begin{aligned} \psi_{,11} \equiv \frac{\partial}{\partial x} \left( \frac{\partial \psi}{\partial x} \right) &= \cos^2 \phi \frac{\partial \alpha_r}{\partial r} - \cos \phi \sin \phi \frac{\partial \alpha_\phi}{\partial r} + \frac{\sin^2 \phi}{r} \alpha_r \\ &\quad - \frac{\sin \phi \cos \phi}{r} \frac{\partial \alpha_r}{\partial \phi} + \frac{\sin \phi \cos \phi}{r} \alpha_\phi + \frac{\sin^2 \phi}{r} \frac{\partial \alpha_\phi}{\partial \phi}, \end{aligned} \quad (36)$$

$$\begin{aligned} \psi_{,22} \equiv \frac{\partial}{\partial y} \left( \frac{\partial \psi}{\partial y} \right) &= \sin^2 \phi \frac{\partial \alpha_r}{\partial r} + \cos \phi \sin \phi \frac{\partial \alpha_\phi}{\partial r} + \frac{\cos^2 \phi}{r} \alpha_r \\ &\quad + \frac{\sin \phi \cos \phi}{r} \frac{\partial \alpha_r}{\partial \phi} - \frac{\sin \phi \cos \phi}{r} \alpha_\phi + \frac{\cos^2 \phi}{r} \frac{\partial \alpha_\phi}{\partial \phi}, \end{aligned} \quad (37)$$

$$\begin{aligned} \psi_{,12} \equiv \frac{\partial}{\partial y} \left( \frac{\partial \psi}{\partial x} \right) &= \sin \phi \cos \phi \frac{\partial \alpha_r}{\partial r} - \sin^2 \phi \frac{\partial \alpha_\phi}{\partial r} - \frac{\sin \phi \cos \phi}{r} \alpha_r \\ &\quad + \frac{\cos^2 \phi}{r} \frac{\partial \alpha_r}{\partial \phi} - \frac{\cos^2 \phi}{r} \alpha_\phi - \frac{\sin \phi \cos \phi}{r} \frac{\partial \alpha_\phi}{\partial \phi} \\ &= \frac{\partial}{\partial x} \left( \frac{\partial \psi}{\partial y} \right) \equiv \psi_{,21}. \end{aligned} \quad (38)$$

In the above expressions, it can be shown that

$$\begin{aligned} \frac{\partial \alpha_r}{\partial r} &= -\frac{\kappa_0}{r} I^{(0)}(r) + \frac{\kappa_0}{r} I'^{(0)}(r) \\ &\quad - \frac{\kappa_0}{r} \sum_{m=1}^{\infty} \cos[m(2\phi - \delta)] \left[ (2m+1)I_{2m}^{(1)}(r) + (2m-1)I_{2m}^{(2)}(r) - 4I_{2m}^{(3)}(r) \right], \end{aligned} \quad (39)$$

$$\frac{\partial \alpha_r}{r \partial \phi} = -\frac{2\kappa_0}{r} \sum_{m=1}^{\infty} \sin[m(2\phi - \delta)] \left[ mI_{2m}^{(1)}(r) - mI_{2m}^{(2)}(r) \right], \quad (40)$$

$$\frac{\partial \alpha_\phi}{\partial r} = -\frac{\kappa_0}{r} \sum_{m=1}^{\infty} \sin[m(2\phi - \delta)] \left[ (2m+1)I_{2m}^{(1)}(r) - (2m-1)I_{2m}^{(2)}(r) \right] \quad (41)$$

and

$$\frac{\partial \alpha_\phi}{r \partial \phi} = \frac{2\kappa_0}{r} \sum_{m=1}^{\infty} \cos[m(2\phi - \delta)] \left[ mI_{2m}^{(1)}(r) + mI_{2m}^{(2)}(r) \right], \quad (42)$$

where we have introduced two new functions:

$$I'^{(0)}(r) = 2h(r)[\varepsilon_2(r)]^\mu {}_2F_1(-\mu, -\mu; 1; \varepsilon_1(r)), \quad (43)$$

and

$$I_{2m}^{(3)}(r) = \left( -\frac{Q}{|Q|} \right)^m (m+\mu) \zeta_2(m, \mu) h(r) [\varepsilon_1(r)]^{\frac{m}{2}} [\varepsilon_2(r)]^\mu {}_2F_1(m-\mu, -\mu; m+1; \varepsilon_1(r)). \quad (44)$$

The magnification factor is then

$$\mathcal{M} = \frac{1}{1 - (\psi_{,11} + \psi_{,22}) + \psi_{,11} \psi_{,22} - \psi_{,12}^2}. \quad (45)$$

The coefficient functions of the deflection angle and magnification factor, equations (26) - (28) (and equations [43] and [44]), contain a hypergeometric function of the same form  ${}_2F_1(j - k - \mu, -k - \mu; j + 1; x)$  with  $k + \mu > -1$  and  $j = 0, 1, 2, \dots$ . The hypergeometric function converges for any  $|x| \leq 1$ . One can prove that the series converges rapidly after about the  $n$ -th order, where  $n \approx k + \mu + 1$  and higher order terms than  $2n$  are almost negligible. Thus, one can evaluate the hypergeometric function easily by truncating the series somewhere after  $2n$ , depending on the accuracy desired. Furthermore, once the value of the function for a  $k$  is known, the function values for other values of  $k$  can be calculated using the Gauss recurrence relations (see, e.g., Abramowitz & Stegun 1964).

For the calculation of light travel time difference (i.e. time delay) between an image pair, say at  $(r_1, \phi_1)$  and  $(r_2, \phi_2)$  on the lens plane, one needs to calculate the difference of  $F(r)$  (eq. [12]) at the two points, i.e.  $F(r_1) - F(r_2) = \int_0^{2\pi} d\phi' \int_{r_1}^{r_2} \kappa(r', \phi') \ln r' \cdot r' dr'$  as well as the other coefficients (equations [7] - [11]). For the expression used to determine the time delay the reader is referred to SEF [equations (5.11) and (5.44)].

### 3. Critical Curves and Caustics of Power-Law Lenses

Our results can be used to see how the case of an arbitrary value of  $\nu$  differs from the best-studied case of  $\nu = 2$  (i.e. the isothermal lenses studied by Kormann et al. 1994 and Kassiola & Kovner 1993) in the structure of critical curves and caustics. The geometry and number of images are determined by the structure of the caustics on the source plane. For isothermal lenses, Kormann et al. (1994) showed that five different types of caustics are possible in the 2-dimensional parameter space spanned by axis ratio  $f$  (which is related to the ellipticity  $\epsilon$  via  $\epsilon = 1 - f$ ) and core radius. In particular, the simple expressions for the deflection enabled them to map out the parameter space in terms of the types of caustics (see their Fig. 9). Here we use examples to study the effect of varying radial index  $\nu$  as well as ellipticity and core radius on the behavior of critical curves and caustics.

We compare three different values of  $\nu$  including the isothermal case for the same ellipticities and core radii (Figures 1, 2, and 3). This provides us with a qualitative understanding of the difference between shallower and steeper distributions of mass. The case of  $\epsilon = 0.7$  and  $r_c = 0.5$  in Fig. 1 shows one liplike (i.e.

of the diamond shape) caustic which we call the first caustic. For  $\epsilon = 0.5$  and  $r_c = 0.5$ , the second caustic of a liplike (or pseudo-elliptic) shape appears inside the first caustic. For  $\epsilon = 0.3$  and  $r_c = 0.5$ , two cusps of the first caustic are inside the second caustic while the other two are “naked” outside and the second caustic is of an elliptical shape. At this stage the second caustic is called “radial” while the first caustic is called “tangential” (see, e.g., SEF). A further decrease of  $\epsilon$  for the same value of  $r_c$  causes the tangential caustic to be completely inside the radial caustic (for  $\epsilon = 0.1$  and  $r_c = 0.5$ ). The last and trivial case is that there is no caustic. This happens when we sufficiently increase either  $\epsilon$  or  $r_c$  from the case of  $\epsilon = 0.7$  and  $r_c = 0.5$  in Fig. 1. In the case of no caustic, multiple imaging is impossible. When there is one liplike caustic, three images become possible. When two caustics exist, up to five images are possible.

For a given value of  $\nu$  the critical behavior can be summarized as follows. For sufficiently large ellipticity and core radius, no caustics exist (thereby no critical curves). As we decrease either ellipticity or core radius, the first caustic comes into existence. A further decrease gives birth to the second caustic, which grows as either ellipticity or core radius decreases, finally enclosing the tangential caustic completely for a sufficiently small ellipticity or core radius.

The effect of varying radial index  $\nu$  on the critical behavior can be qualitatively understood by comparing Figures 1, 2, and 3. For example, for  $\epsilon = 0.7$  and  $r_c = 0.5$ , the case  $\nu = 1.5$  has one liplike caustic. For the same ellipticity and core radius, the isothermal case has two caustics. For  $\nu = 2.5$ , two cusps of the tangential caustic are inside the radial caustic (i.e. the second caustic is grown relative to the first caustic). Now the significance of  $\nu$  on the critical structure is evident. For given ellipticity and core radius, a sufficiently shallow profile does not allow any caustic. As the profile steepens, the first caustic will appear, then the second caustic, and finally the radial caustic will enclose the tangential caustic completely.

#### 4. Discussion and Conclusion

We obtained the complete expressions for the deflection angle and magnification factor as (rapidly) converging series for the triaxial mass distribution of equation (14) and for the elliptical surface density of equation (19). The calculation of an angle (eq. [34]) at a point on the image plane requires evaluations of three functions which are given by equations (26), (27) and (28). For the calculation of the magnification (eq. [45]) one needs to evaluate two additional functions (equations [43] and [44]). Since they converge very rapidly all these functions can be easily evaluated. The hypergeometric function in equations (26),

(27), (28), (43) and (44), which is a well-behaved converging series, can be evaluated rapidly. For instance, one can evaluate the hypergeometric function by summing up less than tens of terms. However, since the hypergeometric function should be evaluated a number of times (namely, the function should be called many times) for the calculation of the deflection and magnification, the execution speed in our approach depends on how the hypergeometric function is evaluated. If one evaluates the hypergeometric function solely by summing up terms, it typically takes about one milli-second for the calculation of the deflection and magnification at a time on a current (SPARC20) unix machine with a fractional uncertainty of about  $10^{-5}$  or better. For example, if the deflection angle is one arcsecond, then the calculational error is about one hundredth milli-arcsecond or smaller with the execution speed specified above.

Now that our results have been presented, one can ask how well the mass model (eq. [14] or eq. [19]) resembles the true mass distribution of a real lens. An application of our results to the Einstein Cross (Q2237+0305), which is known to be lensed by an isolated barred spiral galaxy, shows that the model is a good approximation to the true mass distribution (Chae et al. 1998). In most of the other lensed systems external perturbations are known to be important (Keeton et al. 1997). Thus, unless the external perturbations are taken into account properly in fitting observational constraints, it is not possible to judge whether or not the mass model is a good description of the true mass distribution. There have been numerous lens modeling examples where isothermal models were used.<sup>2</sup> The mass distributions of lenses in nature may differ only slightly from isothermal distributions. However, lenses in the universe will not, in general, exactly mimic isothermal distributions. Thus, it is worthwhile to consider arbitrary values of  $\nu$ . The model we considered here encompasses the isothermal model as a special case (i.e.  $\nu = 2$ ) but allows us to vary the parameter  $\nu$  from the isothermal value.

In conclusion, the following are what we consider to be the most notable aspects of our results.

1. The model we have considered represents the most general case of the familiar power-law mass distributions. It can be considered as a generalization of the isothermal model. Hence, our results can be used to model various single mass distributions (e.g. elliptical/spiral galaxies) until more physical mass models are developed.
2. The resulting expressions for the deflection angle and magnification factor are exact, and no approximations were made in any steps of the calculation.

---

<sup>2</sup>We do not list those examples here because there are many.

3. The series expressions for the deflection angle and magnification factor converge rapidly and can be easily evaluated with the desired accuracies.

## Appendices

### A. The Series Coefficients of the Deflection Angle

We evaluate the coefficients of the deflection angle defined in §2.1, i.e., equations (7) - (11), for the surface mass distribution of equation (19). All of the odd-numbered coefficients vanish because the surface density has symmetry under  $\phi \rightarrow \phi + \pi$ . Hence we set  $n = 2m$  ( $m = 1, 2, 3, \dots$ ).

We define  $g(\phi') \equiv P + Q \sin(2\phi' + S)$  for convenience. Equation (8) becomes

$$B_{2m}(r) = \kappa_0 \int_0^{2\pi} d\phi' \cos(2m\phi') \frac{r^{2(m+1)}}{2(m+1)} \frac{1}{[1 + g(\phi')r^2]^{\mu+1}} \times {}_2F_1\left(\mu+1, 1; m+2; \frac{g(\phi')r^2}{1 + g(\phi')r^2}\right), \quad (\text{A1})$$

where  ${}_2F_1(a, b; c; x)$  is the hypergeometric function. We write out the hypergeometric function as a series and use the binomial expansion to obtain

$$\begin{aligned} \frac{B_{2m}(r)}{r^{2m}} &= \frac{\kappa_0 r^2}{2(m+1)} \sum_{k=0}^{\infty} \frac{(\mu+1)_k}{(m+2)_k} \int_0^{2\pi} d\phi' \cos(2m\phi') \frac{[r^2 g(\phi')]^k}{[1 + r^2 g(\phi')]^{k+\mu+1}} \\ &= \frac{\kappa_0 r^2}{2(m+1)} \sum_{k=0}^{\infty} \frac{(\mu+1)_k}{(m+2)_k} \sum_{l=0}^k \int_0^{2\pi} d\phi' \cos(2m\phi') \binom{k}{l} \frac{[1 + r^2 g(\phi')]^{k-l} (-1)^l}{[1 + r^2 g(\phi')]^{k+\mu+1}} \\ &= \frac{\kappa_0 r^2}{2(m+1)} \sum_{k=0}^{\infty} \sum_{l=0}^k \frac{(\mu+1)_k}{(m+2)_k} \binom{k}{l} (-1)^l \\ &\quad \times \int_0^{2\pi} \frac{\cos 2m\phi'}{[1 + r^2 P + r^2 Q \sin(2\phi' + S)]^{l+\mu+1}} d\phi', \end{aligned} \quad (\text{A2})$$

where  $(a)_b$  is the pochhammer symbol, namely  $(a)_b = \Gamma(a+b)/\Gamma(a)$ . The evaluation of the integral in equation (A2) can be found in Appendix B. So we have

$$\begin{aligned} \frac{B_{2m}(r)}{r^{2m}} &= \frac{\kappa_0 r^2}{2(m+1)} \sum_{k=0}^{\infty} \sum_{l=0}^k \frac{(\mu+1)_k}{(m+2)_k} \binom{k}{l} (-1)^l \cos[m(\pi/2 - S)] \left(\frac{Q}{|Q|}\right)^m 2\pi \\ &\quad \times \frac{[(1 + r^2 P)^2 - (r^2 Q)^2]^{-(l+\mu+1)/2}}{(-l-\mu)_m} P_{l+\mu}^m \left(\frac{1 + r^2 P}{\sqrt{(1 + r^2 P)^2 - (r^2 Q)^2}}\right), \end{aligned} \quad (\text{A3})$$

where  $P_{l+\mu}^m(z)$  is the associated Legendre function. The argument  $z \left[ \equiv (1 + r^2 P) / \sqrt{(1 + r^2 P)^2 - (r^2 Q)^2} \right] \geq 1$  and by analytic continuation (Gradshteyn & Ryzhik 1994) it can be shown that

$$\begin{aligned} P_{l+\mu}^m(z) &= \left( \frac{z-1}{z+1} \right)^{-\frac{m}{2}} \left( \frac{z+1}{2} \right)^{l+\mu} \lim_{\gamma \rightarrow -(m-1)} \frac{{}_2F_1(-l-\mu, -l-\mu-m; \gamma; \frac{z-1}{z+1})}{\Gamma(\gamma)} \\ &= \frac{(-l-\mu)_m (-l-\mu-m)_m}{m!} \left( \frac{z-1}{z+1} \right)^{\frac{m}{2}} \left( \frac{z+1}{2} \right)^{l+\mu} \\ &\quad \times {}_2F_1 \left( m-l-\mu, -l-\mu; m+1; \frac{z-1}{z+1} \right). \end{aligned} \quad (\text{A4})$$

After substituting the above expression into equation (A3), we have

$$\begin{aligned} \frac{B_{2m}(r)}{r^{2m}} &= \frac{\kappa_0 \pi r^2}{m+1} \sum_{k=0}^{\infty} \sum_{l=0}^k \frac{(\mu+1)_k}{(m+2)_k} \binom{k}{l} (-1)^l \cos[m(\pi/2 - S)] \left( \frac{Q}{|Q|} \right)^m \frac{(-l-\mu-m)_m}{m!} \\ &\quad \times \frac{1}{[(1+Pr^2)^2 - (Qr^2)^2]^{(l+\mu+1)/2}} \left( \frac{z-1}{z+1} \right)^{\frac{m}{2}} \left( \frac{z+1}{2} \right)^{l+\mu} \\ &\quad \times {}_2F_1 \left( m-l-\mu, -l-\mu; m+1; \frac{z-1}{z+1} \right). \end{aligned} \quad (\text{A5})$$

Using the defined functions of  $r$  (equations [30] and [31]) and the relation  $(-l-m-\mu)_m = (-1)^m (l+\mu+1)_m$ , we have

$$\begin{aligned} \frac{B_{2m}(r)}{r^{2m}} &= \cos[m(\pi/2 - S)] \kappa_0 \pi r \left( -\frac{Q}{|Q|} \right)^m \frac{1}{(m+1)!} \frac{r}{\sqrt{(1+Pr^2)^2 - (Qr^2)^2}} [\varepsilon_1(r)]^{\frac{m}{2}} \\ &\quad \times \sum_{k=0}^{\infty} \sum_{l=0}^k (-1)^l \binom{k}{l} \frac{(\mu+1)_k (l+\mu+1)_m}{(m+2)_k} [\varepsilon_2(r)]^{l+\mu} \\ &\quad \times {}_2F_1(m-l-\mu, -l-\mu; m+1; \varepsilon_1(r)). \end{aligned} \quad (\text{A6})$$

As equation (A1) implies, the above expression (eq. [A6]) converges slowly when  $(P - |Q|)r^2$  becomes large, i.e.  $g(\phi')r^2/[1 + g(\phi')r^2] \approx 1$ , while it converges rapidly for small  $r$ . However, equation (A1) can be transformed to an alternative form which converges rapidly for  $r > 1/\sqrt{P - |Q|}$ . This alternative form is given by

$$\begin{aligned} \frac{B_{2m}(r)}{r^{2m}} &= \frac{\kappa_0 r^2}{2(m-\mu)} \int_0^{2\pi} d\phi' \frac{\cos 2m\phi'}{[1 + g(\phi')r^2]^{\mu+1}} {}_2F_1 \left( \mu+1, 1; \mu+1-m; \frac{1}{1 + g(\phi')r^2} \right) \\ &\quad + \frac{\kappa_0 r^2}{2} \frac{\Gamma(m+1)\Gamma(\mu-m)}{\Gamma(\mu+1)} \int_0^{2\pi} d\phi' \frac{\cos 2m\phi'}{[1 + g(\phi')r^2]^{m+1}} \\ &\quad \times {}_2F_1 \left( m+1-\mu, m+1; m+1-\mu; \frac{1}{1 + g(\phi')r^2} \right) \\ &\quad (\mu \text{ not integer}) \\ &= -\cos(m\delta) \kappa_0 \pi r \left( -\frac{Q}{|Q|} \right)^m h(r) [\varepsilon_1(r)]^{\frac{m}{2}} \frac{\Gamma(\mu-m)}{\Gamma(\mu+1)\Gamma(m+1)} \end{aligned}$$

$$\begin{aligned} & \times \left\{ [\varepsilon_2(r)]^\mu \sum_{k=0}^{\infty} \frac{\Gamma(k+m+\mu+1)}{\Gamma(k-m+\mu+1)} [\varepsilon_2(r)]^k {}_2F_1(m-k-\mu, -k-\mu; m+1; \varepsilon_1(r)) \right. \\ & \quad \left. - [\varepsilon_2(r)]^m \sum_{k=0}^{\infty} \frac{\Gamma(k+2m+1)}{\Gamma(k+1)} [\varepsilon_2(r)]^k {}_2F_1(-k, -k-m; m+1; \varepsilon_1(r)) \right\}. \\ & (\mu \text{ not integer}) \end{aligned} \quad (\text{A7})$$

The coefficient  $C_{2m}(r)/r^{2m}$  can be calculated in a very similar way and the resulting expressions are identical to equations (A6) and (A7), except that  $\cos[m(\pi/2 - S)]$  is replaced with  $\sin[m(\pi/2 - S)]$ .

The coefficients  $D_{2m}$  and  $E_{2m}$  can also be calculated in a similar way. We find

$$\begin{aligned} r^{2m} D_{2m}(r) &= \frac{\kappa_0 r^2}{2(m+\mu)} \int_0^{2\pi} d\phi' \cos(2m\phi') \sum_{k=0}^{\infty} \frac{(\mu+1)_k}{(m+\mu+1)_k} \frac{1}{[1+g(\phi')r^2]^{k+\mu+1}} \\ &= \frac{\kappa_0 r^2}{2(m+\mu)} \sum_{k=0}^{\infty} \frac{(\mu+1)_k}{(m+\mu+1)_k} \cos[m(\pi/2 - S)] \left( \frac{Q}{|Q|} \right)^m 2\pi \frac{(-k-\mu-m)_m}{m!} \\ &\quad \times \frac{1}{[(1+Pr^2)^2 - (Qr^2)^2]^{(k+\mu+1)/2}} \left( \frac{z-1}{z+1} \right)^{\frac{m}{2}} \left( \frac{z+1}{2} \right)^{k+\mu} \\ &\quad \times {}_2F_1 \left( m-k-\mu, -k-\mu; m+1; \frac{z-1}{z+1} \right) \\ &= \cos[m(\pi/2 - S)] \kappa_0 \pi r \left( -\frac{Q}{|Q|} \right)^m \frac{\Gamma(m+\mu)}{\Gamma(\mu+1)\Gamma(m+1)} \\ &\quad \times \frac{r}{\sqrt{(1+Pr^2)^2 - (Qr^2)^2}} [\varepsilon_1(r)]^{\frac{m}{2}} [\varepsilon_2(r)]^\mu \\ &\quad \times \sum_{k=0}^{\infty} [\varepsilon_2(r)]^k {}_2F_1(m-k-\mu, -k-\mu; m+1; \varepsilon_1(r)) \\ &= \cos(m\delta) \kappa_0 \pi r I_{2m}^{(2)}(r) \end{aligned} \quad (\text{A8})$$

and  $r^{2m} E_{2m}(r) = \sin(m\delta) \kappa_0 \pi r I_{2m}^{(2)}(r)$ .

From the first line of equation (A8), it is clear that  $I_{2m}^{(2)}(r)$  converges slowly when  $(P+|Q|)r^2 \ll 1$ . This is particularly true for  $m=1$ . For  $m \geq 2$ , the convergence is still acceptable even when  $(P+|Q|)r^2 \ll 1$ . Thus, we give an alternative form of  $I_{2m}^{(2)}(r)$  for  $m=1$ , which converges very rapidly when  $r < 1/\sqrt{P+|Q|}$ :

$$\begin{aligned} I_{2m}^{(2)}(r) &= -\frac{P}{Q} \left( 1 - \sqrt{1 - \left( \frac{Q}{P} \right)^2} \right) r \\ &\quad - \frac{r}{\pi} \sum_{k=1}^{\infty} \frac{(-1)^k}{k} \frac{\Gamma(\mu+k+1)}{\Gamma(\mu+1)} (Pr^2)^k \sum_{l=0}^k \left( \frac{2Q}{P} \right)^l \frac{[1 - (-1)^l][\Gamma(l/2+1)]^2}{\Gamma(k-l+1)\Gamma(l+1)\Gamma(l+2)}. \end{aligned} \quad (\text{A9})$$

The above expression can be obtained by dividing the integration interval of  $r'$  in equation (10) into  $[r, r_1]$  and  $[r_1, \infty]$  where  $r < r_1 < 1/\sqrt{g(\phi')}$ .

The coefficient  $A_0(r)$  is obtained by substituting  $m=0$  into the coefficient  $B_{2m}(r)$ , i.e.

$$A_0(r) = \kappa_0 \pi r \frac{r}{\sqrt{(1+Pr^2)^2 - (Qr^2)^2}} [\varepsilon_2(r)]^\mu \times \sum_{k=0}^{\infty} \sum_{l=0}^k (-1)^l \binom{k}{l} \frac{(\mu+1)_k}{(2)_k} [\varepsilon_2(r)]^l {}_2F_1(-l-\mu, -l-\mu; 1; \varepsilon_1(r)). \quad (\text{A10})$$

From the hypergeometric function in equation (A1), it is obvious that either for a lower order of  $m$  or a larger value of  $r$ , the series will converge more slowly. Indeed, the coefficient  $A_0(r)$  converges very slowly for  $r \gg 1/\sqrt{P-|Q|}$ . However, for large  $r$  the coefficient  $A_0(r)$  can be represented by another form which converges extremely rapidly. This alternative form of  $A_0(r)$  can be obtained from equation (7) (for  $\mu \neq 0$ ). Equation (7) becomes, after the integration over  $r'$ ,

$$A_0(r) = \frac{\kappa_0}{2\mu} \left[ \int_0^{2\pi} d\phi' \frac{1}{g(\phi')} - \int_0^{2\pi} d\phi' \frac{1}{g(\phi')} \frac{1}{[1+r^2g(\phi')]^\mu} \right] \quad (\mu \neq 0).$$

In the above expression, the second term can be easily calculated using  $\frac{1}{A-1} = \frac{1}{A} + \frac{1}{A^2} + \dots$  for  $A > 1$ . So we have

$$A_0(r) = \frac{\kappa_0 \pi}{\mu} \frac{1}{\sqrt{P^2 - Q^2}} - \frac{\kappa_0 \pi}{\mu} \frac{r^2}{\sqrt{(1+Pr^2)^2 - (Qr^2)^2}} \sum_{k=0}^{\infty} [\varepsilon_2(r)]^{k+\mu} {}_2F_1(-k-\mu, -k-\mu; 1; \varepsilon_1(r)) \quad (\text{A11})$$

for  $\mu \neq 0$  and  $r > 1/\sqrt{P-|Q|}$ . When  $\mu = 0$ , for any  $r$

$$A_0(r) = \frac{\kappa_0 \pi}{\sqrt{P^2 - Q^2}} \ln \left[ \frac{\sqrt{P^2 - Q^2} \sqrt{(P^2 - Q^2)r^4 + 2Pr^2 + 1} + (P^2 - Q^2)r^2 + P}{\sqrt{P^2 - Q^2} + P} \right]. \quad (\text{A12})$$

For a circular distribution of mass on the lens plane (i.e.  $Q = 0$ ) all of the coefficients vanish except for  $A_0(r)$ .

## B. Evaluation of Two Integrals

For  $A > |B| (\neq 0)$  we have

$$I_c = \int_0^{2\pi} \frac{\cos 2m\phi}{[A + B \sin(2\phi + C)]^\mu} d\phi$$

$$\begin{aligned}
&= \int_0^{2\pi} \frac{\cos m\phi}{[A + B \sin(\phi + C)]^\mu} d\phi \\
&= \int_{-\pi/2+C}^{3\pi/2+C} \frac{\cos(m\phi) \cos[m(\pi/2 - C)] - \sin(m\phi) \sin[m(\pi/2 - C)]}{(A + B \cos \phi)^\mu} d\phi \\
&= \cos[m(\pi/2 - C)] \int_{-\pi/2+C}^{3\pi/2+C} \frac{\cos m\phi d\phi}{(A + B \cos \phi)^\mu} - \sin[m(\pi/2 - C)] \int_{-\pi/2+C}^{3\pi/2+C} \frac{\sin m\phi d\phi}{(A + B \cos \phi)^\mu} \\
&= \cos[m(\pi/2 - C)] \int_0^{2\pi} \frac{\cos m\phi d\phi}{(A + B \cos \phi)^\mu} - \sin[m(\pi/2 - C)] \int_0^{2\pi} \frac{\sin m\phi d\phi}{(A + B \cos \phi)^\mu}.
\end{aligned} \tag{B13}$$

In the above equation the second term vanishes. We use the following relationship derived from an integral representation of the associated Legendre function (Gradshteyn & Ryzhik 1994)

$$\begin{aligned}
\int_0^{2\pi} \frac{\cos m\phi d\phi}{(A + B \cos \phi)^\mu} &= 2 \int_0^\pi \frac{\cos m\phi d\phi}{(A + B \cos \phi)^\mu} \\
&= 2\pi \left( \frac{B}{|B|} \right)^m \frac{(A^2 - B^2)^{-\mu/2}}{(1 - \mu)_m} P_{-\mu}^m \left( \frac{A}{\sqrt{A^2 - B^2}} \right).
\end{aligned} \tag{B14}$$

We then have

$$I_c = 2\pi \left( \frac{B}{|B|} \right)^m \cos[m(\pi/2 - C)] \frac{(A^2 - B^2)^{-\mu/2}}{(1 - \mu)_m} P_{-\mu}^m \left( \frac{A}{\sqrt{A^2 - B^2}} \right). \tag{B15}$$

Similarly, we have

$$\begin{aligned}
I_s &= \int_0^{2\pi} \frac{\sin 2m\phi}{[A + B \sin(2\phi + C)]^\mu} d\phi \\
&= 2\pi \left( \frac{B}{|B|} \right)^m \sin[m(\pi/2 - C)] \frac{(A^2 - B^2)^{-\mu/2}}{(1 - \mu)_m} P_{-\mu}^m \left( \frac{A}{\sqrt{A^2 - B^2}} \right).
\end{aligned} \tag{B16}$$

Fig. 1.— Critical Curves and Caustics for the radial index  $\nu = 1.5$  (see §2.2). Two different core sizes (arbitrary scale) and four different ellipticities are considered. For  $r_c = 0.5$ , each ellipticity corresponds to a different type of caustic, which shows that caustic type evolves as  $\epsilon$  decreases (see §3). Also note that for a fixed ellipticity, caustic type evolves as  $r_c$  decreases.

Fig. 2.— Critical Curves and Caustics for  $\nu = 2$  (the “isothermal” distribution). The same core sizes and ellipticities as in Fig. 1 are considered. This figure can be compared with Figures 1 and 3 to see how caustic type varies as  $\nu$  varies (see §3).

Fig. 3.— Critical Curves and Caustics for  $\nu = 2.5$ . The same core sizes and ellipticities as in Fig. 1 are considered. This figure can be compared with Figures 1 and 2 to see how caustic type varies as  $\nu$  varies (see §3).
